# My Background

# Welcome to ICECCS 2017

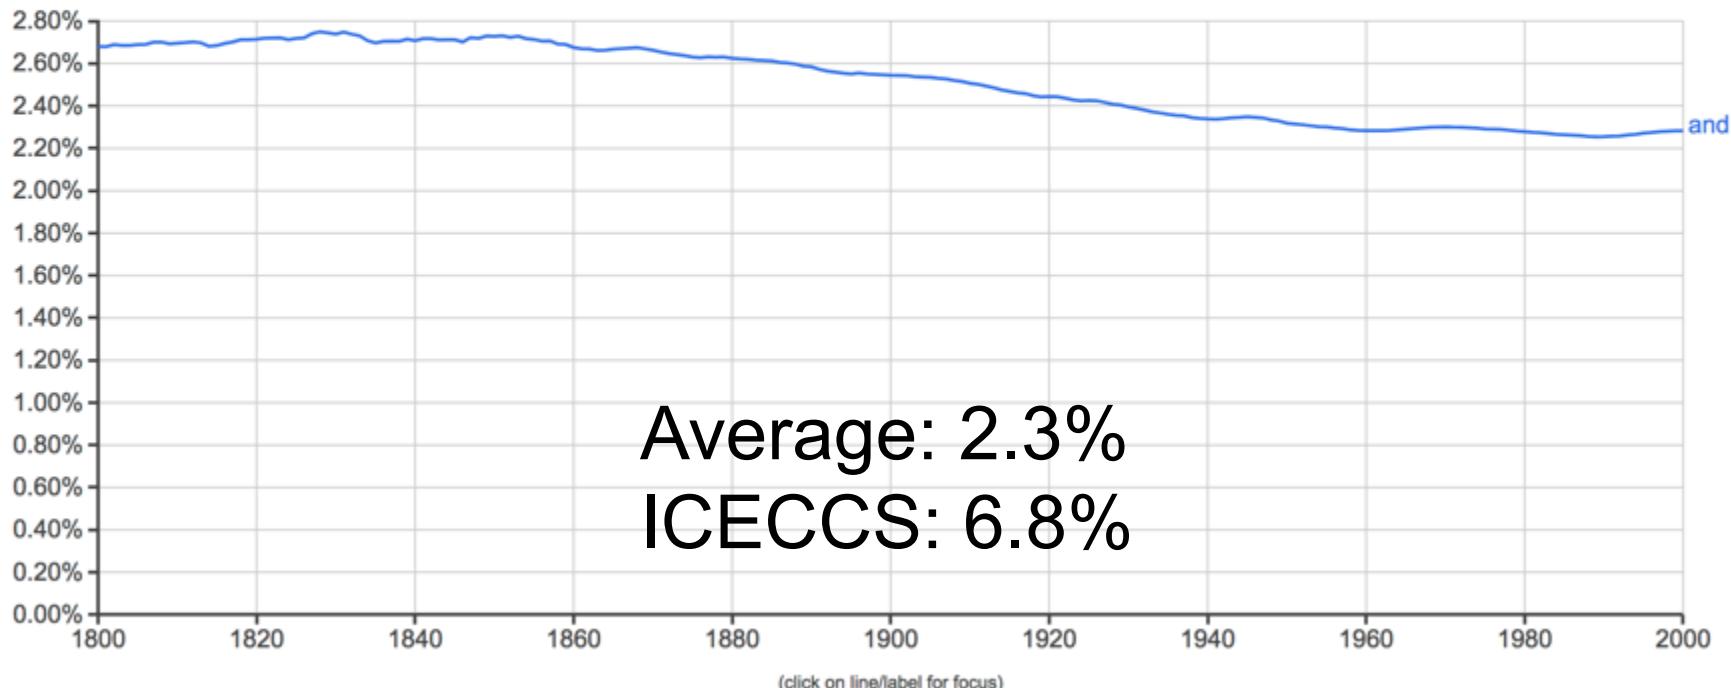

The 22nd International Conference on Engineering of Complex Computer Systems (ICECCS 2017) will be held on November 6-8, 2017, Fukuoka, Japan. Complex computer systems are common in many sectors, such as manufacturing, communications, defense, transportation, aerospace, hazardous environments, energy, and health care. These systems are frequently distributed over heterogeneous networks, and are driven by many diverse requirements on performance, real-time behavior, fault tolerance, security, adaptability, development time and cost, long life concerns, and other areas. Such requirements frequently conflict, and their satisfaction therefore requires managing the trade-off among them during system development and throughout the entire system life. The goal of this conference is to bring together industrial, academic, and government experts, from a variety of user domains and software disciplines, to determine how the disciplines' problems and solution ...

### ABSTRACT

A new and environmentally friendly method for preparation of *N*-substituted pyrroles from one-pot condensation reaction of substituted benzyl aldehydes with amines and diamines in the presence of polystyrene-supported gallium trichloride ( $\text{PSt}-\text{GaCl}_3$ ) as a highly active and reusable heterogeneous Lewis acid catalyst is presented. This new protocol has the advantages of easy availability, stability, reusability and eco-friendly of the catalyst, high to excellent yields, simple experimental and work-up procedure.

### 1. Introduction

Functionalized pyrroles are an important class of nitrogen-containing heterocyclic compounds. They constitute the core unit of many natural products, synthetic materials, and serve as building blocks for porphyrin synthesis [1,2]. Members of this family have wide applications in medicinal chemistry, being used as antimalarial, anti-inflammatory agents, antibacterial, anti-viral [3–5]. These compounds can be prepared from the classical Hantzsch procedure [6], 1,3-dipolar cycloaddition reactions [7],aza-Wittig reactions [8], annulations reactions [9], and other multistep operations [10]. Despite these new developments, the Paal-Knorr reaction remains one of the most significant and simple methods.

This reaction consists the cyclocondensation of primary amines with carbonyl compounds to produce *N*-substituted pyrroles. Several catalysts have been used to promote this reaction including  $\text{HCl}$  [11],  $\text{P-TSA}$  [12],  $\text{HgSO}_4$  [13],  $\text{Sc}(\text{OTf})_3$  [14],  $\text{BF}_3 \cdot \text{OEt}_2$  [15],  $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$  [16],  $\text{Ti}(\text{OPiv})_4$  [17],  $\text{RuCl}_3$  [18],  $\text{InCl}_3$ ,  $\text{InBr}_3$ ,  $\text{In}(\text{OTf})_3$  [19], zeolite [20],  $\text{Al}_2\text{O}_3$  [21], montmorillonite K10 [22], silica sulfuric acid [23], layered zirconium phosphate and phosphonate [24], montmorillonite [25], montmorillonite KSF-clay and  $\text{I}_2$  [26]. Additionally, the above cyclocondensation process could proceed in ionic liquid [27] or ultrasonic and  $\gamma$ -wave irradiation [28]. However, despite the potential utility of these catalysts, many of

these methodologies for the synthesis of pyrroles are associated with several shortcomings such as low yields, prolonged reaction time, harsh reaction conditions, the requirement of excess of catalysts, the use of toxic and detrimental metal precursors as catalysts, and relatively expensive reagents and high temperature, and tedious work-up leading to the generation of large amounts of toxic metal-containing waste. The main disadvantage of almost all existing methods is that the catalysts are destroyed in the work-up procedure and their recovery and reuse is often impossible, which limit their use under the aspect of environmentally benign processes.

Heterogeneous supported catalysts have been gained much attention in recent years, as they possess a number of advantages in preparative procedures [29,30]. Immobilization of catalysts on solid support improves the available active site, stability, hygroscopic properties, handling, and reusability of catalysts which all factors are important in industry [31]. Therefore, use of supported and reusable catalysts in organic transformations has economical and environmental benefits. A large number of polymer-supported Lewis acid catalysts have been prepared by immobilization of the catalysts onto polymer via coordination or covalent bonds [32]. Such polymeric catalysts are usually as active and selective as their homogeneous counterparts while having the distinguishing characteristics of being easily separable from the reaction mixture, recyclability, easier handling, non-toxicity, enhanced stability, and improved selectivity in various organic reactions. Polystyrene is one of the most widely studied heterogeneous and polymeric supports due to its environmental stability and hydrophobic nature

## CCFinder: A Multilingualistic Token-Based Code Clone Detection System for Large Scale Source Code

Toshihiro Kamiya, Member, IEEE, Shinji Kusumoto, Member, IEEE, and Katsuro Inoue, Member, IEEE

**Abstract**—A code clone is a code portion in source files that is identical or similar to another. Since code clones are believed to reduce the maintainability of software, several code clone detection techniques and tools have been proposed. This paper proposes a new clone detection technique, which consists of the transformation of input source text and a token-by-token comparison. For its implementation with several useful optimization techniques, we have developed a tool, named CCFinder, which extracts code clones in C, C++, COBOL, PL/I, and Java files. As well as the usefulness of the proposed technique, we have conducted a series of experiments to evaluate the usefulness of CCFinder and metrics. As a result, CCFinder has effectively found clones and the metrics have been able to effectively identify the characteristics of the systems. In addition, we have compared the proposed technique with other clone detection techniques.

**Index Terms**—Code clone, duplicated code, CADE test, metrics, maintainability.

### 1 INTRODUCTION

A code clone is a code portion in source files that is identical or similar to another. Clones are introduced because of various reasons such as reusing code by “copy-and-paste,” mental macro (definitive computation frequently coded by a programmer in a regular style, such as payroll tax, queue insertion, data structure access, etc.) or attempting to represent a common feature for reuse or enhancement [Fig. 1]. A conservative and protective approach for modification and enhancement of a legacy system would introduce clones. Also, systematic generation of a set of slightly different code portions from a single basic will bear clones. Clones make the source files very hard to modify consistently. For example, let’s assume that a software system has several clone submodules created by dropping a few lines of code from a main module. If there is one submodule, the engineer has to carefully modify all other submodules [15]. For a large and complex system, there are many engineers who take care of each submodule and then modification becomes very difficult. If the existence of clones has been documented and maintained properly, the modification would be relatively easy; however, keeping all clone information is generally a laborious and expensive process. Various clone detection tools have been proposed and implemented [1], [2], [3], [4], [5], [7], [11], [14], [15], [17] and a number of algorithms for finding clones have been used for them, such as line-by-line matching for an abstracted source program [3] and similarity detection for metrics values of function bodies [17].

We were interested in applying a clone detection technique to a large software system, a division of government, which consists of over 2 million lines of code in 2,000 modules written in both COBOL and PL/I-like language, which was developed more than 20 years ago and has been maintained continually by a large number of engineers [18], [19]. It was believed that there would be many clones in the system, but the documentation did not provide enough information regarding the clones. It was considered that these clones heavily reduce maintainability of the system; thus, an effective clone detection tool has been expected.

Based on such initial motivation for clone detection, we have devised a clone detection algorithm and implemented a tool named CCFinder (Code clone finder). The underlying concepts for designing the tool were as follows:

- The tool should be industrial strength and be applicable to a medium-size system within a reasonable computation time and memory usage.
- A clone detection system should have the ability to select clones or to report only helpful information for user to examine clones since large number of clones is expected to be found in large software systems. In other words, the code portions, such as short ones inside single lines and sequence of numbers for table installation, may be clones, but they would not be useful for the users. A clone detection system that removes such clones with heuristic knowledge improves effectiveness of clone analysis process.

# Extending CCFinder

- Prototype was extended, tuned, and refined as a practical tool
- Target languages
  - Initially C
  - Adapted to C++, COBOL, Java, Lisp, Text
- Added GUI and result visualizer

# Promoting Code Clone Technology

---

- Collaboration with many companies
  - NTT, Fujitsu, Hitachi, Samsung, Microsoft Research, ...
- International Workshop on Software Clones IWSC ('02~)
- Code clone seminars (9 times, '02~'07)

## CCFinder

CCFinder is a tool for detecting code clones and has the following features:

### Scalability

CCFinder can be applied to huge source codes. From a source code with approximately a million lines, CCFinder can detect code clones within several minutes to several hours using a PC/AT compatible.

### Applicability to various programming languages

By lexical analysis and transformation based on the syntax of the programming languages, CCFinder can extract code clones correctly from source files, even in cases where the names of variables have been changed. CCFinder can run for C/C++, Java, COBOL, Fortran, etc.

### Designed as a command-line tool

In the early stages of the development of CCFinder, tools such as a converter for gnuplot, i.e. a converter from the output of CCFinder to a format for the input of a gnuplot, were used to display the distribution of detected code clones.

Visual Studio 2015 | [Other Versions](#) ▾

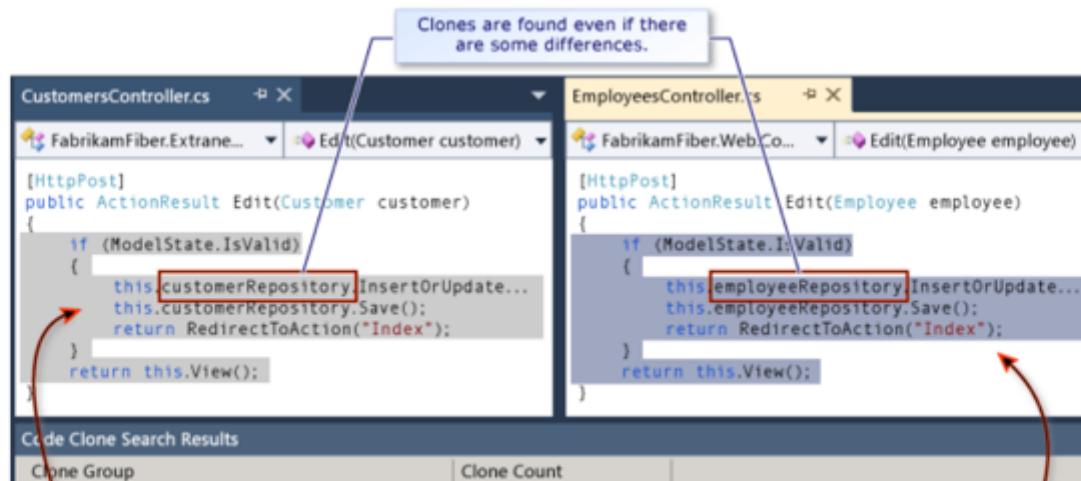

The new home for Visual Studio documentation is [Visual Studio 2017 Documentation](#) on [docs.microsoft.com](#).

The latest version of this topic can be found at [Visual Studio 2017 Documentation](#). **Code clones** are separate fragments of code that are very similar. They are a common phenomenon in an application that has been under development for some time. Clones make it hard to change your application because you have to find and update more than one fragment.

**Visual Studio Enterprise** can help you find code clones so that you can refactor them.

You can either find the clones of a specific fragment, or find all clones in your solution. In addition to discovering direct copies, the clone analysis tool can find fragments which differ in the names of variables and parameters, and in which some statements have been rearranged.

The code clone analyser searches for duplicate code in Visual C# and Visual Basic projects throughout your Visual Studio solution.

Clone Notifierは、バージョン間でコードクローン（ソースコード中の重複コード）の差分情報を検出・可視化するツールです。本システムを利用することによって、コピー・アンド・ペーストによって新しく発生したクローンや、一貫した修正漏れの可能性があるクローンの情報を検出・可視化することができます。詳しい使用方法は <https://osdn.net/projects/clonenotifier/downloads/66557/manual.pdf> を参照ください。

2013年版はすべてCCFinder対応バージョン、Ver.2.0は関数クローン検出ツール対応バージョンです。

## Experience of Finding Inconsistently-Changed Bugs in Code Clones of Mobile Software

Katsuro Inoue†, Yoshiaki Higo†, Norihiro Yoshida†, Eunjong Choi‡, Shinji Kasumoto‡,  
 Kyonghwan Kim‡, Wonjin Park‡, and Eunha Lee‡

 {kyonghwan73.kim, wj23.park, leeeunha}@samsung.com

**Abstract**—When we reuse a code fragment, some of the identifiers in the fragment might be systematically changed to others. Making these changes would become a potential bug in the copied fragment. We have developed a tool *CloneInspector* to detect such inconsistent changes in the code clones, and applied it to two mobile software systems. Using this tool, we were effectively able to find software bugs in these systems.

*Keywords:* Inconsistent Change, Unchanged Ratio, Bug Candidate

## 1. INTRODUCTION

Software systems for mobile phone (mobile software) are becoming huge and complex, and debugging and maintaining them are getting difficult and expensive.

A mobile software system needs to adapt its features to various country/area constraints, and so many code clones

- We have restructured and modified various parts of the prototype tool, and have built a tool named *CloneInspector*.

In this paper, we will show an overview of CloneInspector, and present our experience of applying CloneInspector to Samsung's large mobile software.

## II. CLONEINSPECTOR

Figure 1 shows the process of CloneInspector.

- 1) First, code clones in the input source files are detected by code clone detector CCFinder [2]. The positions of code clones are generated.
  - 2) Using the positions, code fragments for the detected code clones are tokenized. At the same time, the occurrences of identifiers are examined.

## Applications

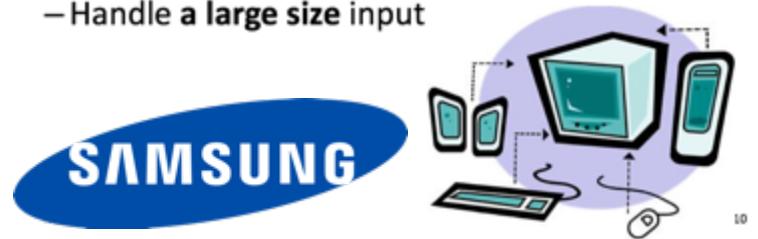

A { Feature : Communication  
Language : C  
Size(LOC) : 4,275,952  
Bug Candidates: 63  
True Bug : 25

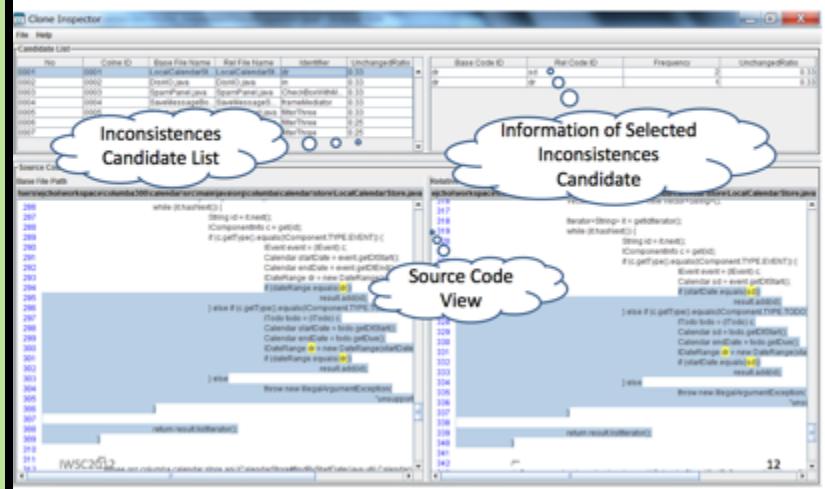

**B** { Feature : Application  
Language : C  
Size(LOC) : 136,554  
**Bug Candidates:** 5  
**True Bug :** 1

## Overview of Clone Inspector

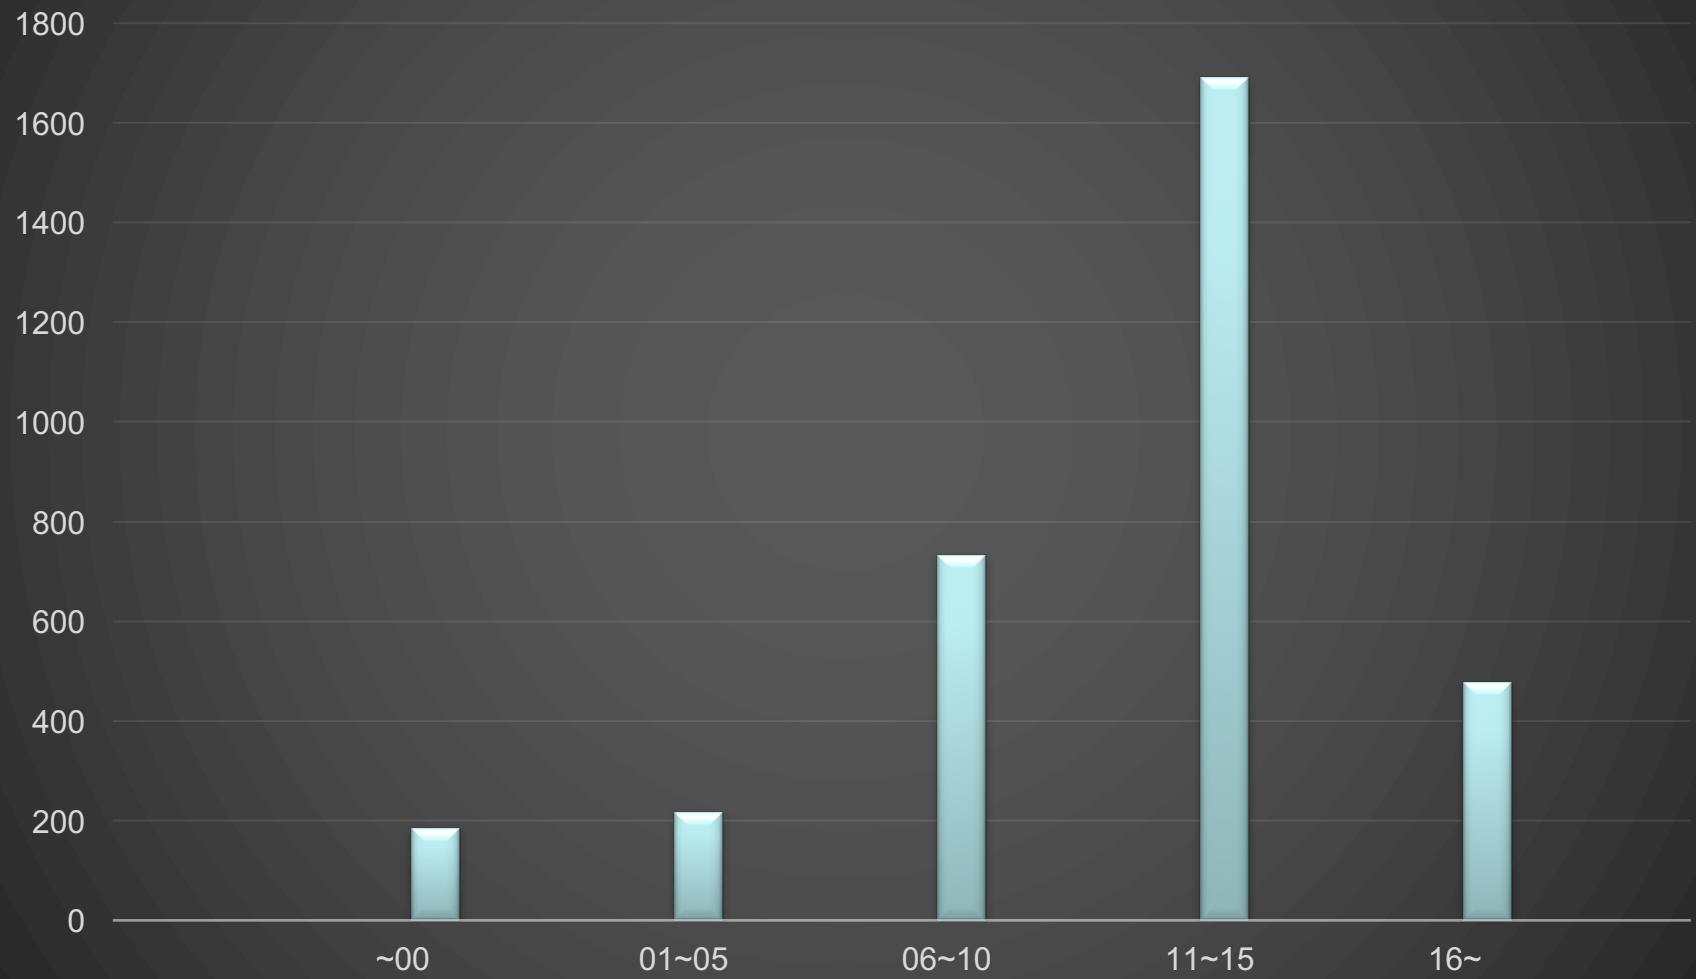

- A tool to fit to the development environment of mobile software in SAMSUNG
    - Detect **inconsistent changes** in code clones
      - Using CCFinder and two metrics
    - Handle a large size input

*{inoue, peixia, y-manabe}@ist.osaka-u.ac.jp*

**Abstract**—When we reuse a code fragment in an open source system, it is very important to know the history of the code, such as the code origin and evolution. In this paper, we propose an integrated approach to code history tracking for open source repositories. This approach takes a query code fragment as its input, and returns the code fragments containing the code clones with the query code. It utilizes publicly available code search engines as external resources. Based on this model, we have designed and implemented a prototype system named *Ichi Tracker*. Using *Ichi Tracker*, we have conducted three case studies. These case studies show the ancestors and descendants of the code, and we can recognize their evolution history.

**Keywords**-Code Search; Software Evolution; Open Source System

### I. INTRODUCTION

*Open source systems* are extremely useful resources for the construction of current software systems. Even software systems in the industry increasingly use open source systems due to their reliability and cost benefits [25].

One of usages of the open source systems is to reuse the source code of the open source systems for other projects. We can easily get the source code files of various projects from the repositories on the Internet, such as SourceForge [29] and Maven Central [26]. Those source code files are

Current software engineering tools do not provide sufficient support to explore code history. To know the code origin, we have to specify project names and/or URLs. Also, to know the code evolution, we have to understand the interrelations of open source projects.

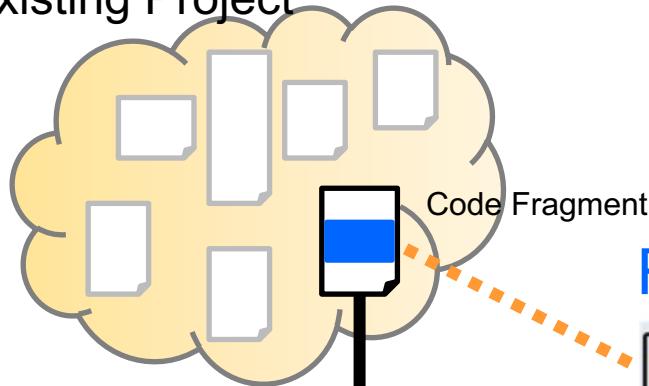

Code search engines such as Google Code Search [10] and Koders [3] are very useful tools to explore open source repositories for the origin and evolution of code. However, current code search engines only allows to get keywords and/or code attributes as their inputs, and they return source code files which contains those keywords and attributes. Selecting appropriate inputs for those search engines is not easy task for general users.

In this paper, we will propose an integrated approach to code history tracking for open source repositories. Also, we will present its prototype system named *Ichi Tracker* (Integrated Code History Tracker). *Ichi Tracker* takes a code fragment as its query input, and returns a set of cloned code fragments which can be found by popular source code search engines such as SPARS/R [30], Google Code Search [10], and Koders [3]. *Ichi Tracker* helps us to understand the backward and forward history of the query code fragment.

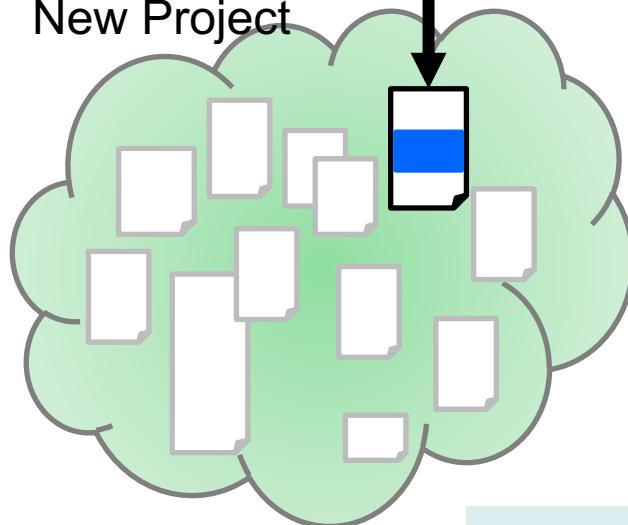

Using *Ichi Tracker*, we have performed various case

## Do developers update their library dependencies? An empirical study on the impact of security advisories on library migration

Raula Gaikovina Kula<sup>3</sup> · Daniel M. German<sup>2</sup> ·  
Ali Ouni<sup>1,4</sup> · Takashi Ishio<sup>3</sup> · Katsuro Inoue<sup>1</sup>

© Springer Science+Business Media New York 2017

**Abstract** Third-party library reuse has become common practice in contemporary software development, as it includes several benefits for developers. Library dependencies are constantly evolving, with newly added features and patches that fix bugs in older versions. To take full advantage of third-party reuse, developers should always keep up to date with the latest versions of their library dependencies. In this paper, we investigate the extent of which developers update their library dependencies. Specifically, we conducted an empirical study on library migration that covers over 4,600 GitHub software projects and 2,700 library dependencies. Results show that although many of these systems rely heavily on dependencies, 81.5% of the studied systems still keep their outdated dependencies. In the case of updating a vulnerable dependency, the study reveals that affected developers are not likely to respond to a security advisory. Surveying these developers, we find that 69% of the
